1 Quick Overview

1.1 Includes

```cpp
#include <iosfwd>   // Only the declaration for input and output streams
#include <istream>  // Implementation of input stream
#include <ostream>  // Implementation of output stream
#include <iostream> // std::cout, std::cin, std::cerr
#include <cctype>   // Functions: std::tolower(c), std::isupper(c)
#include <string>   // Strings
#include <array>
#include <cctype> // lowercase, isalpha,isblank, toupper
#include <vector>
#include <numeric>  // std::iota
#include <iterator> // std::count, std::accumulate, std::distance, std::for_each
#include <functional> // greater, less, logical_and
#include <deque>    // std::deque<T>
#include <list>
#include <forward_list> // std::forward_list<T>
#include <stack>
#include <queue>
#include <stack> // std::priority_queue
#include <set>
#include <map>
#include <unordered_set> // std::unordered_set --> Hashed
#include <unordered_map> // std::unordered_map --> Hashed
#include <memory> // std::unique_ptr / std::shared_ptr (smart pointer)
#include <stdexcept> // out_of_range, runtime_error, range_error
```

1.2   ASCII Table

Dez	Hex	Okt	ASCII	Dez	Hex	Okt	ASCII	Dez	Hex	Okt	ASCII	Dez	Hex	Okt	ASCII

Figure 1: ASCII Table

2 Basic Concepts

2.1 Why C++?

- Work al almost all platforms from a micro controller to the main frame
- Multi-paradigm language with zero-cost abstraction
- High-level abstraction facilities
- The concepts from C++ can mostly be applied to any other programming language

2.2 Features

- C++ doesnt't has no methods only functions. A function does not have to be a member of an object. If a function belongs to an object it's a member function.
- Please do not write your own loops in C++ try to use the STL (Standard Template Library).
- C++ is compatible with standard C.
- There is no Garbage Collector!
- With a library we can publish functionalities to another program.

2.3 Terminology

Value 42

Type int, char, bool, long, float

Variable int const i{42}

Expression (2+4)*3

Statement `while ( true );`

Declaration int foo();

Definition int j;

Function void bar ( ) { }

2.4 Undefined Behaviour

The undefined behaviour is defined in the C++ standard (funny, isn't it?). Because of the fact, that C++ doesn't have a garbage collection, if in C++ something is written wrong and the compiler doesn't detect it: undefined behaviour can occur.

2.5 C++ Compilation Process

C++ has the advantage of direct compilation into machine code. This eliminates the overhead for a virtual machine in comparison to Java.

*.cpp files for source code

- Also called "Implementation File"
- Function implementations (can be in .h files as well)
- Source of compilation - aka "Translation Unit"

*.h files for interfaces and templates

- Called "Header File"
- Declarations and definitions to be used in other implementation files.
- Textual inclusion through a pre-processor (C++20 will incorporate a "Module" mechanism)
- `#include "header.h"`

3 Phases of Compilation

- **Preprocessor** – Textual replacement of preprocessor directives, results in (*.i) files. (`#include`)
- **Compiler** – Translation of C++ code into machine code (source file (*.i) to object file (*.o))
- **Linker** - Combination of object files (*.o) and libraries into libraries and executables (*.exe).

2.6 Declarations and Definitions

All things with a name that you use in a C++ program must be declared before you can do so!

Defining Functions

```
<return-type> <function-name> (<parameters>) \{ /* body */ \}
```

Tells the compiler that there is a function named `<function-name>` that takes the parameters `<parameters>` and returns a value of type `<return-type>`. The Signature of a function is just the combination of name and the parameter types.

One Definition Rule (ODR)

While a program element can be declared several times without problem there can be only one definition of it.

Include Guard

Include guards ensure that a header file is only included once. Multiple inclusions could violate the One Definition Rule when the header contains definitions. Is not required for function declarations but for type definitions in header files.

```
1  #ifndef SAYHELLO_H_
2  #define SAYHELLO_H_
3  #include <iosfwd>
4  struct Greeter {
5  };
6  #endif /* SAYHELLO_H_ */
```

3 Variables

- Variables always start with a lower case character
- Local variables must always contain a default value (Curly brackets or =).
- A global variable must never be mutable! (Hard to test and can cause problems when multithreading is used)
- Variables are as default value types and therefore declared on the stack.

3.1 Definitions

Defining a variable consists of specifying its `<type>`, its `<variable-name>` and its `<initial value>`. Empty braces mean default initialisation. Using = for initialisation we can have the compiler determine its type (do not combine with braces!).

<div align="center">

`<type> <variable-name> {<initial-value>};`

</div>

Constants
Adding the const keyword in front of the name makes the variable a single-assignment variable, aka a constant. A const must be initialised and is immutable.

When should const be used?

- A lot of code needs names for values, but often does not intend to change it
- It helps to avoid reusing the same variable for different purposes (code smell)
- It creates safer code, because a const variable cannot be inadvertently changed
- It makes reasoning about code easier
- Constness is checked by the compiler
- It improves optimization and parallelization (shared mutable state is dangerous)

Where to place Variable definition?
Do not practice to define all (potentially) needed variables up front (that style is long obsolete!). Every mutable global variable you define is a design error!

A Note on Naming
The C++ convention is to begin variable names with a lower case letter. Spell out what the variable is for and do not abbreviate!

Types for Variables
Are part of the language and don't need an include.

- short, int, long, long long – each also available as unsigned version
- bool, char, unsigned char, signed char - are treated as integral numbers as well
- float, double, long double

3.2 Values and Expressions

C++ provides automatic type conversion if values of different types are combined into an expression. Dividing integers by zero is undefined behaviour.

```
1 (5 + 10 * 3 - 6 / 2) // precedence as in normal mathematics = 32
2 auto x = 3; / 3 // Fractions results of int operations always rundet down! 1
3 auto y = x%2 ? 1 : 0; // int boolean conversion 0=false, others are true.=1
```

3.3 Const

- Const should be used as often as possible for non-member variables, because it optimises the code.
- Const is comparable with the final from Java, although it has a higher guarantee that the variable is not changed.
- Const variables must be initialized!
- Const variables are immutable!
- Some constants are required to be fixed at compile time → to enforce this use `constexpr`.

```
1 double constexpr pi{3.14159};
```

Literal Example	Type	Value
'a'	char	Letter a, value: 97
'\n'	char	<NL> character, value: 10
'\x0a'	char	<NL> character, value: 10
1	int	1
42L	long (grösser)	42
5LL	long long	5
int{} (not really a literal)	int	0 (default value)
1u	unsigned int	1
42ul	unsigned long	42
5ull	unsigned long long	5
020	int	16 (octal 20)
0x1f	int	31 (hex 1F)
0XFULL	unsigned long long	15 (hex F)
0.f	float	0
.33	double	0.33
1e9	double	1000000000 (10^9)
42.E-12L	long double	0.00000000042 ($42*10^{-12}$)
.31	long double	0.3
"hello" (n+1)	char const [6]	Array of 6 chars: h e l l o <NUL>
"\012\n\\"	char const [4]	Array of 4 chars: <NL> <NL> \ <NUL>

Figure 2: C++ Variable Types

3.4   Auto

The keyword auto can be used to deduct the type of a variable automatically at the declaration.

```
1 auto const yearOfBirth = 2049; // int
2 auto const name = "Rick Deckard" // std::string
```

3.5   Strings

std::string is C++'s type for representing sequences of char (which is often only 8 bit). This Strings are mutable in C++ in contrast to Java. Literals like "ab" are not of type std::string they consist of const chars in a null terminated array.

To have a std::string we need to append an **s**. This requires using namespace std::literals;. This is important when we want to deduce types.

```
1  void printName(std::string name) {
2    using namespace std::literals;
3    std::cout << "my name is: "s << name;
4 }
```

String Capabilites
You can iterate over the contents of a string.

```
1 void toUpper(std::string & value) {
2   for (char & c : value) {
3     c = toupper(c);
4   }
5 }
6
7 void toUpper(std::string & value) {
8   transform(cbegin(value), cend(value), begin(value), ::toupper);
9 }st
```

4 Streams

- In the header files the inclusion of `#include <iosfwd>` forward declaration header. This is sufficient for function declarations.
- In a source file for `std::cin` and `std::cout` the `#include <iostream>` should be used. If just one of the two stream objects is need use either `#include <ostream>` or `#include <istream>`. The last two dont include the "std::cin" and "std::cout".
- In the main function "std::cin" and "std::cout" is used with the corresponding shift operators "«", "»".
- "std::istream" objects do return false if we are in an invalid stream state.
- "std::endl" flushes a buffered out stream. Better use "\n".

4.1 Input and Output Streams

Functions taking a stream object must take it as a reference, because they provide a side-effect to the stream (i.e., output characters).

Simple I/O
Stream objects provide C++'s I/O mechanism with the help of the pre-defined globals: std::cin std::cout. Streams have a state that denotes if I/O was successful or not.

- Only `.good()` streams actually do I/O
- You need to `.clear()` the state in case of an error
- Reading a `std::string` can not go wrong, unless the stream is already `!good()`.

Reading a std::strting Value

```cpp
#include <iostream>
#include <string>
  std::string inputName(std::istream & in) {
    std::string name{};
    in >> name;
    return name;
}
```

Reading an int Value

```cpp
int inputAge(std::istream& in) {
  int age{-1};
  if (in >> age) { // Boolean conversion
  return age;
  }
  return -1;
}
```

Chaining Input Operations

- Multiple subsequent reads are possible
- If a previous read already failed, subsequent reads fail as well

```cpp
std::string readSymbols(std::istream& in) {
  char symbol{};
  int count{-1};
  if (in >> symbol >> count) {
    return std::string(count, symbol);
  }
  return "error";
}
```

Robust Reading of an int Value

```cpp
int inputAge(std::istream & in) {
  std::string line{};
  while (getline(in, line)) {
    std::istringstream is{line};
```

```
 5      int age{-1};
 6      if (is >> age) {
 7        return age;
 8      }
 9    }
10    return -1;
11 }
```

4.2   Stream States

Formatted input on stream is must check for is.fail() and is.bad(). If failed, is.clear() the stream and consume invalid input characters before continue.

State Bit Set	Query	Entered
<none>	is.good()	initial is.clear()
failbit	is.fail()	formatted input failed
eofbit	is.eof()	trying to read at end of input
badbit	is.bad()	unrecoverable I/O error

Figure 3: Stream States in C++

Dealing with invalid Input

```
 1 int inputAge(std::istream & in) {
 2   while(in.good()) {
 3     int age{-1};
 4     if (in >> age) {
 5       return age;
 6     }
 7     in.clear(); // remove failed flag
 8     in.ignore(); // ignore one char
 9   }
10   return -1;
11 }
```

4.3   Manipulators

For the formatting of the output a vide variety of manipulator can be used. These manipulators are defined in `#include <iomanip>`.

Manipulator	Input / Output	Beschreibung
`std::dec`	beides	sets integer format to decimal
`std::oct`	beides	sets integer format to octal
`std::hex`	beides	sets integer format to hexadecimal
`std::showpos`	beides	show plus sign for positive numbers
`std::noshowpos`	beides	do not show plus sign
`std::showbase`	beides	sets integer format to show base
`std::noshowbase`	beides	sets integer format to not show base
`std::uppercase`	beides	use upper case for hex digits, exponent etc
`std::nouppercase`	beides	use lower case for hex digits, exponent etc
`std::boolalpha`	beides	use "true" and "false" for bool
`std::noboolalpha`	beides	use 1 and 0 for bool i/o
`std::setw(n)`	beides	sets next field width to n, non sticky
`std::setfill(c)`	output	sets output field fill character
`std::left`	output	output towards the left in a wider field, fill character on the right
`std::right`	output	output towards the right in a wider field, fill character on the left
`std::internal`	output	fill character between sign/base and number
`std::scientific`	beides	sets floating point format with exponent
`std::fixed`	beides	sets fixed floating point format without exponent
`std::defaultfloat`	beides	sets default floating point format
`std::setprecision(n)`	beides	sets significant or fractional number of digits
`std::showpoint`	output	include floating point always
`std::noshowpoint`	output	omit floating point if possible
`std::flush`	output	flush buffered output
`std::endl`	output	output newline and flush buffered output
`std::ends`	output	output `'0'` and flush buffered output

Figure 4: C++ Manipulatoren für Streams [Michael Wieland]

5 Iterators

There are always two iterators used `begin() end()`. There is also the possibility to traverse a list from front to back `rbegin() rend()`. If the members are only read the const version `cbegin() cend()` can be used.

5.1 Iteration

Its possible to index a vector like an array but there is no bounds check. Accessing an element outside the valid range is Undefined Behavior.

Bad Style Iteration!

```
1 for (size_t i = 0; i < v.size(); ++i) {  //Index is "unsigned" 0-1=MAX_INT
2   std::cout << "v[" << i << "] = " << v[i] << '\n'; }
3 }
```

Element Iteration (Range-Based for)

- Advantage: No index error possible
- Works with all containers, even value lists 1, 2, 3

	const: • element cannot be changed	non-const: • element can be changed

reference:
 • element in vector
 is accessed
	`for (auto const & cref : v) {`
	 `  std::cout << cref << '\n';`
	 `}`
		`for (auto & ref : v) {`
		 `  ref *= 2;`
		 `}`

copy:
 • loop has own copy
 of the element
	`for (auto const ccopy : v) {`
	 `  std::cout << ccopy << '\n';`
	 `}`
		`for (auto copy : v) {`
		 `  copy *= 2;`
		 `  std::cout << copy << '\n';`
		 `}`

Iteration with Iterators

Elements can be accessed with `*iterator`.

```
1 for (auto it = std::begin(v); it != std::end(v); ++it) {
2   std::cout << (*it)++ << ", ";
3 }
4 // Guarantee to just have read-only access with std::cbegin() and std::cend()
5 for (auto it = std::cbegin(v); it != std::cend(v); ++it) {
6   std::cout << *it << ", ";
7 }
```

5.2 Using Iterators with Algorithms

Each algorithm takes iterator arguments. The algorithm does what its name tells us. The most used ones are `std::accumulate, std::distance`.

```
1 // Counting blanks in a string
2 size_t count_blanks(std::string s) {
3   size_t count{0};
4   for (size_t = 0; i < s.size(); ++i) {
5     if (s[i] == " ") {
6       ++count;
7     }
8   }
9   return count;
10 }
11
12 // Counting blanks in a string with algorithms
```

```
13 size_t count_blanks(std::string s) {
14   return std::count(s.begin(), s.end(), " ");
15 }
16
17 // Summing up all values in a vector
18 std::vector<int> v{5, 4, 3, 2, 1};
19 std::cout << std::accumulate(std::begin(v), std::end(v), 0)<< " = sum\n";
20
21 // Number of elements in range
22 void printDistanceAndLength(std::string s) {
23   std::cout << "distance: "<< std::distance(s.begin(), s.end()) <<'\n';
24   std::cout << "in a string of length: "<< s.size()<<'\n';
25 }
26
27 // Printing all values of a vector
28 void printAll(std::vector<int> v) {
29   std::for_each(std::crbegin(v), std::crend(v), print);
30 }
31
32 // For each with a Lambda
33 void printAll(std::vector<int> v, std::ostream & out) {
34   std::for_each(std::crbegin(v), std::crend(v), [&out](auto x) {
35     out << "print: "<< x << '\n';
36   });
37 }
```

5.3   Iterators for I/O

Iterators connect streams and algorithms. Streams (std::istream and std::ostream) cannot be used with algorithms directly.

- `std::ostream_iterator<T>` outputs values of type T to the given std::ostream
- No end() marker needed for output, it ends when the input range ends.
- `std::istream_iterator<T>` reads values of type T from the given `std::istream`
- End iterator is the default constructed `std::istream_iterator<T>`
- It ends when the stream is no longer good().

```
1 std::copy(std::begin(v), std::end(v), std::ostream_iterator<int>{std::cout, ", "});
2 // In order to use shorter names we can use an alias
3 using input =  std::istream_iterator<std::string>;
4 input eof{};
5 input in{std::cin};
6 std::ostream_iterator<std::string> out{std::cout, " "};
7 std::copy(in, eof, out);
```

5.4   Unformatted Input

The `std::istream_iterator<T>` has the disadvantage, that it skips white space. In order to avoid that we need to use `std::istreambuf_iterator<char>`. This is for char types only!

```
1 using input = std::istreambuf_iterator<char>;
2 input eof{};
3 input in{std::cin};
4 std::ostream_iterator<char> out{std::cout, " "}; std::copy(in, eof, out);
```

5.5   Types

There are five different types of iterators in C++.

```
1 struct input_iterator_tag { };
2 struct output_iterator_tag { };
3 struct forward_iterator_tag : public inputer_iterator_tag { };
4 struct bidirectional_iterator_tag : public forward_iterator_tag {};
5 struct random_access_iterator_tag : public bidirectional_iterator_tag { };
```

5.5.1 Input Iterator

- The element can be read only once and after that the iterator has to be incremeneted.
- Used for `std::istream_iterator` and `std::istreambuf_iterator`

5.5.2 Forward Iterator

- Element can be read in and changed (Except element or container is const).
- Only allows forward iteration
- Sequenz can be iterated over multiple times

5.5.3 Bidirectional Iterator

- Element can be read in and changed (Except element or container is const).
- Allows forward and backwards iteration
- Sequenz can be iterated over multiple times
- The random access iterator behaves as the bidirectional iterator with the addition that the can access elements over the index

5.5.4 Output Iterator

- Current element can be changed once, after that the iterator has to be incremented.
- There is no end for this iterator (example console prints)
- Used for `std::ostream_iterator`
- Writes the result without knowing the result.

5.6 Iterator Functions

There are a number of functions defined in `#include <iterator>` to be used with an iterator.

std::distance() counts the number of "hops" iterator start must make until it reaches goal

std::advance() lets the iterator hop n times.

std::next moves to iterator to the next element. Makes a copy of the argument.

```cpp
int main() {
  std::vector<int> primes{2, 3, 5, 7, 11, 13};
  auto current = std::begin(primes);
  auto afterNext = std::next(current);  // step size 1
  std::cout << "current: " << *current << " afterNext: " << *afterNext << '\n';

  std::advance(current, 1);  // Custom step size
  std::cout << "current: " << *current << " afterNext: " << *afterNext << '\n';
}
```

We can therefore loop with the help of iterators. Please prefer algorithmgs over this.

```cpp
std::vector<int> v{3, 1, 4, 1, 5, 9, 2, 6};
for (auto it = cbegin(v); it != cend(v); ++it) {
  std::cout << *it << " is " << ((*it % 2) ? "odd" : "even") << '\n';
}
```

6 Functions

- Functions are always written in lower Camel Case
- A function must be declared always in a header file before the function is used
- A good function has a maximum of five parameters and does exactly one thing
- The call sequence of the function parameters is not defined.
- The main function does implicit return a "0".
- Auto should not be used as a return type, exceptions are: inline, template or constexpr functions in header files.
- Void should not be used as a function parameter
- NEVER return a ref to a local variable since it produces a dangling Reference, because the value lives in the stack frame.

6.1 Default Arguments

A function declaration can provide default arguments for its parameters *from the right.*

```
1 void incr(int & var, unsigned delta = 1);
2 // Default arguments can be omitted  calling
3 int counter {0};
4 incr(counter); // uses default for delta
```

6.2 Function Overloading

The same function name can be used for different functions if parameter number or types differ. Function can not be overloaded just by their return type! If only the parameter type is different there might be ambiguities. The resolution fo overloads happens at compile-time = Ad hoc polymorphism.

```
1 void incr(int & var);
2 int incr(int & var); // doesn't compile because of same signature
3 void incr(int & var, unsigned delta);
```

6.3 Reference / Value Arguments

Parameter Declarations

	const: • Parameter cannot be changed	non-const: • Parameter can be changed
reference: • Argument on call-site is accessed	```void f(std::string const & s) {` ` //no modification` ` //efficient for large objects` `}```	```void f(std::string & s) {` ` //modification possible` ` //side-effect also at call-site` `}```
copy: • Function has its own copy of the parameter	```void f(std::string const s) {` ` //no modification` ` //used for maximum constness` `}```	```void f(std::string s) {` ` //modification possible` ` //side-effect only locally` `}```

- Value Parameter - Default `void f(type par)`
- Reference Parameter - side-effect `void f(type & par)`
- Const-Reference Parameter - optimisation `void f(type const & par)`
- Const Value Parameter - Prevent changing the parameter in the function `void f(type const par)`.

Function Return Type

- By Value - default `type f()`
- By Const Value - don't do this! `type const f()`.
- By Reference - Only return a reference parameter (or a call member variable from a member function) `type & f()` or `type const & f()`.

Functions as Parameters

Functions are "first class" objects in C++. You can pass them as augment and you can keep them in reference variables.

6.3.1   Function return type deduction

In function definitions the return type can be declared auto. The actual return type will be deduced from the return statements in the function's body, the body must be present for that!!

If the return type of a function is declared as auto a trailing return type can specify the return type. In this case the function body is not required when specifying a trailing return type.

```
1 auto middle(std::vector<int> const & c) -> int;
2 auto isOdd = [](auto value) -> bool {
3   return value % 2;
4 };
```

6.4   Variadic Arguments

Variadic functions take a variable number of arguments. This example is even a template function with variadic arguments.

```
1 template<typename First, typename...Types>
2 void printAll(First const & first, Types const &...rest) {
3   std::cout << first;
4   if (sizeof...(Types)) {
5     std::cout << ", ";
6   }
7   printAll(rest...);
8 }
```

6.5   Lambdas

- Can be written into variables `auto l = [](); l();`
- The smallest lambda is `[](){}` the first two brackets are the function object and the round brackets the call.

Defining Inline functions. Auto const for function variable for Lambda. [] introduces a Lambda function. Can contain captures: [=] or [&] to access variables from scope.

```
1 auto const g = [](char c) -> {
2   return std::toupper(c);
3 };
4 g('a');
```

6.5.1   Captures

Captured variables are imutable default. To change them they have to be declared as `mutable`. Captures are need to use variables outside of the lambda.

- `[=]` - default implicit capture variables used in body by value
- `[&]` - default capture variable used in body by reference
- `[var = value]` - introduce new capture variable with value
- `[=,& out]` - capture all by copy, out by reference
- `[&, = x]` - capture all by reference, but x by copy/value

```
1  // Capturing by value
2  int x = 5;
3  auto l = [x]() mutable {
4    std::cout << ++x;
5  };
6  // Capuring by reference
7  auto const l = [&x]() {
8    std::cout << ++x;
9  };
10
```

```cpp
11 // Capturing all local variables by Value
12 auto l = [=]() mutable {
13   std::cout << x++;
14 };
15 // Capturing all local variables by reference
16 auto l = [&]() mutable {
17   std::cout << x++;
18 };
19
20 // New local variable can be specified in capture
21 auto squares = [x=1]() mutable {
22   std::cout << x *= 2;
23 };
```

6.6 Functor

Functors are types which provide an operation. Functors have an overloaded call operator. Lambdas internally work with functors. The `operator()` function can theoretically be overload as often as needed.

```cpp
1 struct Accumulator {
2   int count{0};
3   int accumulated_value{0};
4   void operator()(int value) {
5     count++;
6     accumulated_value += value;
7   }
8   int average() const {
9     return accumulated_value / count;
10   }
11   int sum() const;
12 };
13
14 int average(std::vector<int> values) {
15   Accumulator acc{};
16   for(auto v : values) { acc(v); }
17   return acc.average();
18 }
19 int main(int argc, char **argv) {
20   std::vector<int> values { 1, 2, 6, 4, 5, 3 };
21   std::cout << average(values);
22 }
```

6.7 Predicates

A function or a lambda returning bool (or a type convertible to bool). Is used to check a criterion or a condition.

```cpp
auto is_odd = [](int i) -> bool {return i % 2;};
```

Figure 5: Unary Predicate

Figure 6: Binary Predicate

7 Exceptions

An exception can throw any copyable type. There is no check if you catch an exception that might be thrown at call-site. Exception thrown while exception is propagated results in a program abort (not while caught).

7.1 Failing Functions

What should we do, if a function cannot fulfil its purpose?

1. Ignore the error and provide potentially undefined behaviour
2. Return a standard result to cover the error
3. Return an error code or error value
4. Provide an error status as a side-effect
5. Throw an Exception

Ignore the Error

- Relies on the caller to satisfy all preconditions.
- Viable only if not dependent on other resources.
- Most efficient implementation.
- Simple for the implementer but hard for the caller.

Cover the Error with a Standard Result

- Reliefs the caller from the need to care if it can continue with the default value
- Can hide underlying problems.
- Often better if caller can specify its own default value.

Error Value

- Only feasible if result domains is smaller than return type
- POSIX defines -1 to mark failure of system calls
- Burden on the caller to check the result

Cover the Error with a Standard Result

- Requires reference parameter
- (Bad!) Alternative: global variable (POSIX: errno)
- E.g: std::istreams's states (good(), fail()) is changed as a side-effect of input

7.2 Catching Exceptions

Principle: Throw by value, catch by const reference. This avoids unnecessary copying and allows dynamic polymorphism for class types.

```cpp
#include <stdexcept> // contains some sublcasses
try {
throw std::logic_error("message");
} catch (type const & e) {
  //Handle type exception
} catch (type2 const & e) {
  //Handle type2 exception
} catch (...) {
  //Handle other exception types
}
```

The Standard Library has some pre-defined exception types that you can also use in <stdexcept>. All have a constructor parameter for the "reason" of type std::string. It provides the what() member function to obtain the "reason"
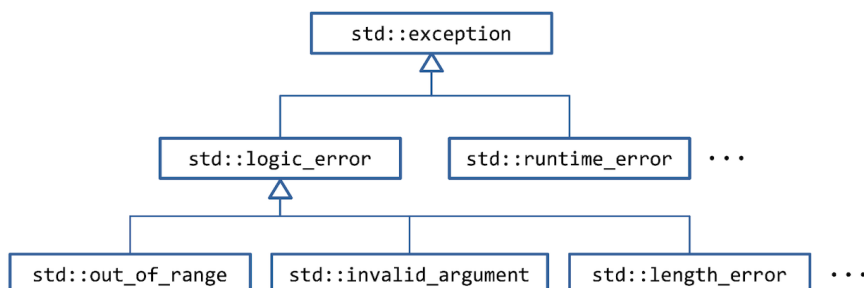

7.3   Keyword noexcept

Functions can be declared to explicitly not throw an exception with the noexcept keyword. The compiler does not need to check it. If an exception is thrown (directly or indirectly) from a noexcept function the program will terminate.

```cpp
int add(int lhs, int rhs) noexcept {
  return lhs + rhs;
}
// -------
void fail() {
  throw 1;
}
void lie() noexcept {
  fail(); // program fails
}
```

8 Classes

Are defined in header files and not in *.cpp files! The implementation can then be done in a suitable file.

- Class members are implicitly inline.
- A class does one thing well and is named after that.
- A class consists of member functions with only a few lines.
- Has a class invariant: provides guarantee about its state (values of the member variables).
- Don't make member variables const as it prevents copy assignment. Don't add members to communicate between member function calls.
- Member functions should when possible be const, as long as they don't change the this object

```cpp
class <GoodClassName> {
  <member variables>
  <constructor>
  <member function>
};
```

Class type in a header file.

```cpp
#ifndef DATE_H_
#define DATE_H_
class Date {
  int year, month, day;
public:
  Date() = default;
  Date(int year, int month, int day) : year{year}, month{month}, day{day});
  static bool isLeapYear(int year);

private:
  bool isValidDate() const;
};
#endif /* DATE_H_ */
```

Implementation of the class.

```cpp
#include "Date.h"
Date::Date(int year, int month, int day) : year{year}, month{month}, day{day} {
    if (!isValidDate()) {
      throw std::out_of_range{"invalid date"};
    }
  }

Date::Date() : Date{1980, 1, 1} { } // Default constructor

Date::Date(Date const & other) : Date{other.year, other.month, other.day} { } // copy
    constructor

bool Date::isLeapYear(int year) {
  /* ... */
}
```

8.1 Access Specifier

- private: visible only inside the class (and friends); for hidden data members
- protected: also visible in subclasses
- public: visible from everywhere; for the interface of the class

Static Member Functions and Variables
No *static* in *.cpp file only in *.h file!

8.2 Constructors

Function with name of the class and no return type.

- Default Constructor - No parameters. Implicitly available if there are no other explicit constructors. Has to initialize member variables with default values.

- Copy Constructor - Has one <own-type> const & parameter. Implicitly available (unless there is an explicit move constructor or assignment operator). Copies all member variables.

- Move Constructor - Has one <own-type> && parameter. Implicitly available (unless there is an explicit copy constructor or assignment operator). Moves all members

- Typeconversation Constructor - Has one <other-type> const & parameter. Converts the input type if possible. Declare explicit to avoid unexpected conversions.

- Initializer List Constructor - Has one std::initializer_list parameter. Does not need to be explicit, implicit conversion is usually desired. Initializer List constructors are preferred if a variable is initialized with { }

- Destructor - Named like the default constructor but with a ∼. Must release all resources. Implicitly available. Must not throw an exception. Called automatically at the end of the block for local instances.

```cpp
class Date {
public:
    Date(int year, int month, int day);
    Date(); // Default-Constructor implicitly available if no other ctor
    Date() = default; // explizit Default-Constructor
    Date(Date const &); // Copy-Constructor
    Date(Date &&); // Move-Constructor
    explicit Date(std::string const &); // Typeconversion-Constructor
    Date(std::initializer_list<T> elements); // Initializer List-Constructor
    ~Date(); // Destructor
    Date(Date const &) = delete; // delete implicit Copy-Constructor
};
```

8.2.1 Defaulted Constructor

In order no to state the default constructor explicitly in the cpp file it can be defined in the header file of the class. This is also possible for the move and the copy constructor. This makes sure we don't have to implement it again.

```cpp
#ifndef DATE_H_
#define DATE_H_
class Date {
  int year{9999}, month{12}, day{31};
  //...
  Date() = default;
  Date(int year, int month, int day);
};
#endif /* DATE_H_ */
```

8.2.2 Deleted Constructors

Some special member functions/constructors are implicitly avaiable in member classes and this is not alway wanted. We can hide this functions or mark them as deleted.

```cpp
class Banknote {
  int value;
  //...
  Banknote(Banknote & const) = delete; // deleted copy ctor
};
```

8.2.3   Delegating Constructors

Similar to Java constructors can call other constructors.

```cpp
#include <Date.h>
Date::Date(int year, int month, int day) : Date{year, Month(month), day} {}
```

8.3   Member Functions

Don't violate the invariant! Every Class has a implicit `this->member-variable` object. It is allowed to call const member functions from non-const member functions but not visa-versa!

8.4   Static

8.4.1   Static Member Functions

Have no `this` object, Cannot be const in implementation! And have no `static` keyword in implementation.

```cpp
#include <Date.h>
bool Date::isLeapYear(int year) { // no static in implementation!
  return !(year % 4) && ((year % 100) || !(year % 400));
}
```

8.4.2   Static Member Variables

Also no `static` keyword in implementation. static const member can be initialized directly.

```cpp
class Date {
  static const Date myBirthday;
  static Date favoriteStudentB;
};

#include <Date.h>
Date const Date::myBirthday{2049, 01, 01};
Date::favoriteStudent{1452, 05, 02};
```

8.5   Inline Functions

Inline function is a function that is expanded in line when it is called. When the inline function is called whole code of the inline function gets inserted or substituted at the point of inline function call. This substitution is performed by the C++ compiler at compile time. Inline function may increase efficiency if it is small (All the functions defined inside the class are implicitly inline).

8.6   Friend Functions

A friend function can be given a special grant to access private and protected members. Even though the prototypes for friend functions appear in the class definition, friends are not member functions.

8.7   Inheritance

Base classes are specified after the name: `class <name> : <base1>, ... , <baseN>`. Multiple inheritance is possible and inheritance can specify visibility. If no visibility is specified the default of the inheriting class is used.

```cpp
class Base {
private:
  int onlyInBase;
protected:
  int baseAndInSubclasses;
public:
  int everyoneCanFiddleWithMe
};
class Sub : public Base {
```

```
10    //Can see baseAndInSubclasses and
11    //everyoneCanFiddleWithMe
12  };
```

Make sure to always check the default inheritenace visibilty!

```
1  struct Vehicle {
2    Location location{};
3  };
4  class Car : Vehicle { // class inherits implicity private!
5  public:
6    Route drive(Destination destination);
7  };
8  void printLocation(Car & car) {
9    std::cout << car.location; // this field is private and cant be accessed!
10 }
```

9 Operator Overloading

Custom operators can be overloaded for user-defined types. Declared like a function, with a special name: <returntype> operator op(<parameters>);. Unary operators -> one parameters and binary operators -> two parameters. In this example we want to make a Date comparable.

9.1 Free Operator

Free operator< uses two parameters of Date each *const* & return type *bool*. Must be inline when defined in header. The only problem we have is that we don't have access to private members.

```cpp
// File Any.cpp
#include "Date.h" Any.cpp
#include <iostream>
void foo() {
  std::cout << Date::myBirthday;
  Date d{};
  std::cin >> d;
  std::cout << "is d older? " << (d < Date::myBirthday);
}

// File Date.h
class Date {
  int year, month, day; // private :-(
};
inline bool operator<(Date const & lhs, Date const & rhs) {
  return lhs.year < rhs.year ||  // Does not WOKR!
  (lhs.year == rhs.year && (lhs.month < rhs.month ||
    (lhs.month == rhs.month && lhs.day == rhs.day)));
}
```

9.2 Member Operator

Member operator< uses one parameter of type *Date*, which is *const&*, return type *bool* and Right-hand side of operation. Implicit this object: *const* due to qualifier, left-hand side of operation. Is implicit inline!

```cpp
// File Any.cpp
#include "Date.h"
#include <iostream>
void foo() {
  std::cout << Date::myBirthday;
  Date d{};
  std::cin >> d;
  std::cout << "is d older? " << (d < Date::myBirthday);
}
// File Date.h
class Date {
  int year, month, day; // private :-)
  bool operator<(Date const & rhs) const {
  return year < rhs.year ||
  (year == rhs.year && (month < rhs.month ||
  (month == rhs.month && day == rhs.day)));
  }
};
```

9.2.1 Implementing All Operators

Best practice is to define one member operator and build the free operators with the member operator.

```cpp
// word.h
class Word {
private:
  std::string word;

```

```cpp
 6 public:
 7   Word() = default;
 8   Word(std::string word);
 9
10   std::ostream & print(std::ostream & os) const;
11   std::istream & read(std::istream & is);
12   // Member operator as a basis for all other operators
13   bool operator<(Word const & rhs) const; // implicit inline
14   std::ostream & print(std::ostream & os) const {
15     os << year << "/" << month << "/" << day;
16     return os;
17   }
18 }
19
20 };
21
22 inline std::ostream & operator<<(std::ostream & os, Word const & word) {
23   return word.print(os);
24 }
25
26 inline std::istream & operator>>(std::istream & is, Word & word) {
27   return word.read(is);
28 }
29
30 inline bool operator>(Word const & lhs, Word const & rhs) {
31   return rhs < lhs;
32 }
33
34 inline bool operator>=(Word const & lhs, Word const & rhs) {
35   return !(lhs < rhs);
36 }
37
38 inline bool operator<=(Word const & lhs, Word const & rhs) {
39   return !(rhs < lhs);
40 }
41
42 inline bool operator==(Word const & lhs, Word const & rhs) {
43   return !(lhs < rhs) && !(rhs < lhs);
44 }
45
46 inline bool operator!=(Word const & lhs, Word const & rhs) {
47   return !(lhs == rhs);
48 }
49
50 // word.cpp
51 bool Word::operator<(Word const & rhs) const {
52   return std::lexicographical_compare(word.begin(), word.end(), rhs.word.begin() ,rhs
     .word.end(), [](char lhs, char rhs) {
53     return std::tolower(lhs) < std::tolower(rhs);
54   });
55 }
```

10 Enums

- Enums can be used for types that hold a few values.
- Every enum field can be converted into an int, starting with the 0.
- The names of an Enum cant be given out as default. For this a lookuptable is needed.
- With the class keyword (Scoped Enum) the type of the enum is not visible outside the namespace. The normal unscoped Enum is visible outside the namespace.

```cpp
enum [class] <name> {
  <enumerators>
};

enum class day_of_week {
  Mon, Tue, Wed, Thu, Fri, Sat, Sun // 0 - 6

  day_of_week operator++ (day_of_week & aDay) {
    int day = (aDay + 1) % (Sun + 1); // Convertion to int
    aDay = static_cast<day_of_week>(day);
    return aDay;
  }
};
```

10.1 Arithmetic Types

Disclaimer: You usually do not want to implement your own arithmetic types! Examples: Rings, Finite Fields.

```cpp
struct Ring5 {
  explicit Ring5(unsigned x = 0u)
    : val{x % 5}{}
  unsigned value() const {
    return val;
  }
private:
  unsigned val;
};
```

11   Namespaces

- Namespaces are scopes for grouping and preventing name clashes.
- Global namespaces has the :: prefix.
- Nesting of namespaces is possible.
- Nesting of scopes allows hiding of names.
- Namespaces can only be defined outside of classes and functions.
- The same same namespace can be opened and closed multiple times.
- Qualified names are. used to access names in a namespace: `demo::subdemo::foo()`
- A name with a leading :: is called fully qualified name: ::std::cout.
- `using namespace` shouldn't be used.

```cpp
namespace demo {
void foo(); //1
namespace subdemo {
void foo() {/*2*/}
} // subdemo
} // demo

namespace demo {
void bar() {
  foo(); //1
  subdemo::foo(); //2
}
}

void demo::foo() { /*1*/ } // definition

int main() {
  using demo::subdemo::foo;
  foo(); //2
  demo::foo(); //1
  demo::bar();
}
```

11.1   Using Declaration

- Import a name from a namespace into the current scope
  - That name can be used without a namespace prefix
  - Useful if the name is used very often
- Alternative: using alias for types if name is long
- There are also using directives, which import ALL names of a namespace into the current scope.
  - Use them only in local scope to avoid "pollution" of your namespace.

```cpp
using std::string;
string s{"no std::"};
int main() {
  using namespace std; // local scope to avoid pollution
  cout << "Hello John";
}
```

11.2   Anonymous Namespaces

- Special case: omit name after namespace
- Implicit using directive for the chosen stream
- Hides modules internals
- Use them only in source files (*.cpp)

11.3   Name Resolution of Namespace Members

Types and (non-member) functions belonging to that type should be placed in a common namespace. The Advantage is *Argument Dependent Lookup! ADL:* When the compiler encounter an unqualified function or operator call with an argument of a user-defined type it looks into the namespaces in which that type is defined to resolve the functionoperator. E.g. it is not necessary to write std:: in front of for_each when std::vector::begin() is an argument of the function.

```
namespace one {                           adl.h     #include "adl.h"                    adl.cpp
  struct type_one{};
  void f(type_one){/*...*/}                          int main() {
}                                                      one::type_one t1{};
                                                       f(t1);
namespace two {                                        two::type_two t2{};
  struct type_two{};                                   f(t2);
  void f(type_two) {/*...*/}                           h(t1);
  void g(one::type_one) {/*...*/}                      two::g(t1);
  void h(one::type_one) {/*...*/}                      g(t1);   //Argument type does not match
}                                                      g(t2);
                                                     }
void g(two::type_two) {/*...*/}
```
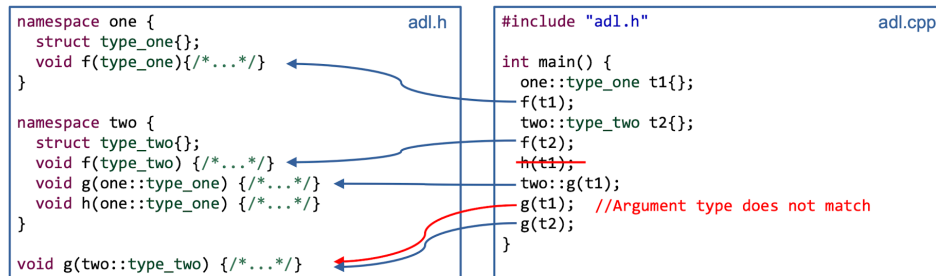

Figure 7: Argument Dependent Lookup Example

11.4   Arithmetic Types

Disclaimer: You usually do not want to implement your own arithmetic types! We will cover the basics.

- Arithmetic types must be equality comparable
- Boost can be used to get != operator $\rightarrow$ boost::equality_comparable
- It might be convenient to have the output operator
- Result must be in a specific range (Modulo)

12 Container and Collections

**Container** Contains objects with value (vector, string, set, map)

Collection Contains objects by reference

- Container can be copied easily using the constructor (deep copy). `std::vector<int> vv{};`
- Container support the "clear()" function which empty the container.
- There are three types of containers: Sequence Containers, Associative Containers and Hashed Containers.
- With containers member function should be preferred over STL.
- Two containers with the same type can be compared `c1 == c2`

Containers can be: default-constructed, copy-constructed from another container of the same type, equality compared, emptied with clear().
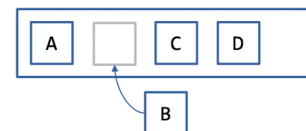

Sequence Containers

- Elements are accessible in order as they were inserted/created.

- Find in linear time through the algorithm find.

- `vector, dequq, list, array`
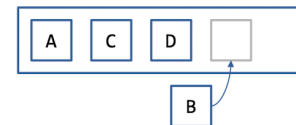

Associative Containers

- Elements are accessible in sorted order

- `find` as member function in logarithmic time.

- `set, multiset, map, multimap`.

Hashed Containers

- Elements are accessible in unspecified order

- `find` as member function in constant time.

- `unorered_map, unordered_multimap, unordered_set, unorderd_multiset`
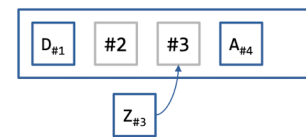

Member Function	Purpose
begin() end()	Get iterators for algorithms and iteration in general
erase(iter)	Removes the element at position the iterator `iter` points to
insert(iter, value)	Inserts value at the position the iterator `iter` points to
size() empty()	Check the size of the container

Figure 8: Member Function of a Container

12.1 Common Container Constructors

Containers can be: default constructed, copy-constructed, equality compared, clear();

```cpp
// Constructor with Initializer List
std::vector<int> v{1,2,3,5,6,11};
// Construction with a number of elements, five times a 42
std::list<int> l(5,42);
// Range with a pair of iterators
std::deque<int> q{begin(v), end(v)};
```

12.2   Array

C++'s `std::array<T, N>` is a fixed-size Container. T is a template type parameter (= placeholder for type). N is a positive integer, template non-type parameter (= placeholder for a value). Elements can be accessed with a subscript operator `[]` `at()`. The size is bound to the array object and can be queried using .size();.
Avoid plain C-array whenever possible: `int arr[]{1, 2, 3, 4, 5};`

- `at()` throws an exception on invalid index access
- `[]` has undefined behavior on invalid index access Behavior
- The size of an array must be known at compile-time and cannot be changed. Otherwise it contains N default-constructed elements.
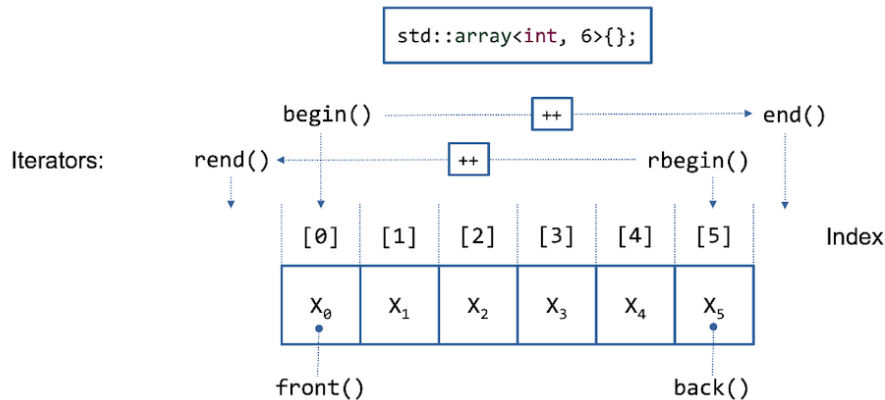

12.3   Vector

- C++'s `std::vector<T>` is a Container = contains its elements of type T (no need to allocate them).
- The elements are allocated on the heap.
- If a vector is passed to a function we can prevent a copy when we pass it as const.
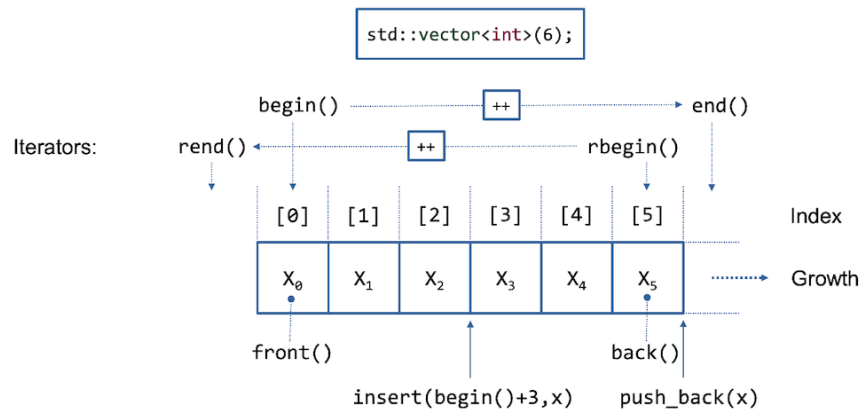

Append Elements to an std::vector<T>

- `v.push_back(<value>);`
- `v.insert (<iterator-position>, <value>);`

Filling a Vector with Values

```
std::vecor<int> v{};
v.resize(10);
std::fill(std::begin(v), std::end(v), 2);

std::vector<int> v(10);
std::fill(std::begin(v), std::end(v), 2);

```

```
8  std::vector v(10, 2);
9
10 // Filling increased values with iota
11 std::vector<int> v(100); std:iota(std::begin(v), std::end(v), 1);
```

Finding and counting elements of a vector
std::find() and std::find_if() return an iterator to the first element that matches the value or condition.

```
1  auto zero_it = std::find(std::begin(v), std::end(v), 0); if (zero_it == std::end(v))
      {
2  std::cout << "no zero found \n"; }
```

12.4   Double-Linked List

- Very efficient inserting at any position.
- Lower efficiency in bulk operations.
- Only bi-directional iterators - no index access

Figure 9: Double-Linked List

```
1  std::list<int> l = { 7, 5, 16, 8 };
2  l.push_front(25);
3  l.push_back(13);
4  // Insert an integer before 16 by searching
5  auto it = std::find(l.begin(), l.end(), 16);
6  if (it != l.end()) {
7    l.insert(it, 42);
8  }
```

12.5   Singly-Linked List

- Efficient insertion AFTER any position, but clumsy with iterator to get "before" the position.
- Only supports forward iteration.
- Avoid, except when there is a specific need! better use double-linked list.

Figure 10: Singly-Linked List
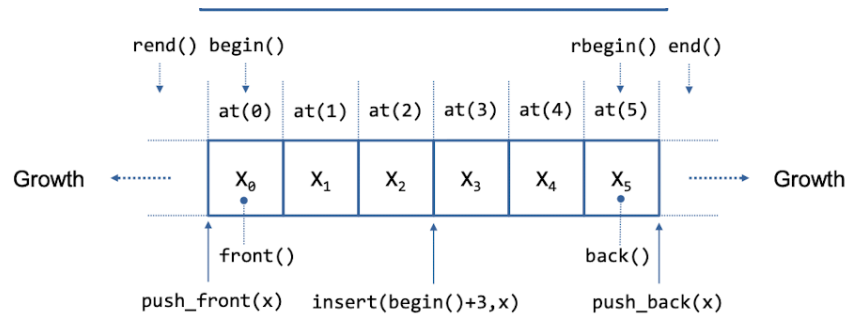

```
1  std::list<int> l (5, 1);
```

Figure 11: Deque

12.6   Double-ended Queue (Deque)

Are like a vector, but additionally elements can be added efficiently to the start of the container.

12.7   Stack, LIFO Adapter

- Uses a double ended queue (or vector, list) and limits its functionality to stack operations.
- Iteration is not possible!

Figure 12: Stack

```cpp
std::stack<int> s{};
s.push(42);
std::cout << s.top();
s.pop();
```

12.8   Queue, FIFO Adapter

In contrast to the Stack takes "pop()" the element from the begin of the Queue.

Figure 13: Queue

```cpp
std::queue<int> q{};
q.push(42);
std::cout << q.front();
q.pop();
```

12.9   Set

The set does save all the elements in a tree. As a result there are no duplicates and all the elements are sorted automatically.

```cpp
#include <set>
std::set<int> s {7,1,4,3,2,5,6};

#include <string>
#include <algorithm> -> transform
#include <iostream> -> cout
#include <iterator> -> ostream_iterator
#include <cctype> -> lowercase

// insert
std::string const input{"test string"};
std::set<char> myset { };
std::transform(input.begin(), input.end(), inserter(myset, myset.begin()), [](char c)
    {
  return tolower(c);
});

// print
std::ostream_iterator<char> out {std::cout}
std::copy(myset.begin(), myset.end(), out};
```

12.10   Unorderet Set

Has no sorting and a more efficient lookup. Standard lacks feature for creating own hash functions.

```cpp
std::unordered_set<char> const vowels{'a', 'e', 'i', 'o', 'u'};
```

12.11   Multiset

In contrast to the set does the multiset allow duplicates.

```cpp
#include <iostream>
#include <iterator>
#include <string>
#include <set>

using in=std::istream_iterator<std::string>;
using out=std::ostream_iterator<std::string>;
std::multiset<std::string> words{in{std::cin},in{}};
copy(cbegin(words), cend(words), out(std::cout, "\n"));
```

12.12   Map

In a map key-value pairs are stored, where the value can be in the set multiple times but the key is unique. Also the keys are stored in ascending order. The over can be overwritten with a 3rd template parameter.

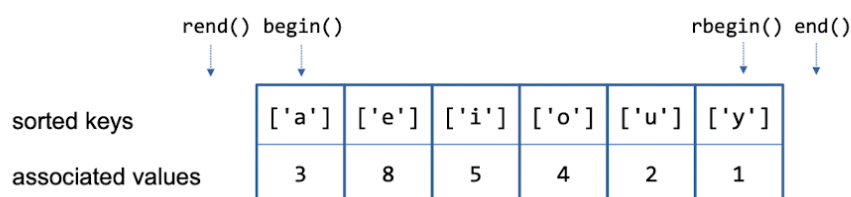

Figure 14: Map

```cpp
std::map<char, size_t> vowels
{{'a',0},{'e',0},{'i',0},{'o',0},{'u',0},{'y',0}};

// Increment Value of Key
++vowels['a'];

// Beim Iterieren ist jedes Element ein pair<char, size>
for(auto const & p:vowels) {
  std::cout << p.first << " = "<< p.second << "\n";
}
```

12.13   Multimap

Allows to have multiple keys.

13 STL Algorithms

The `algorithm.h` are the algorithms defined for general purpose. and in the `numeric.h` are the general numeric functions.

What is are the advantages of the STL algorithms?

- Correctness
  - It is much easier to use an algorithm correctly than implementing loops correctly.
- Readability
  - Applying the correct algorithm expresses your intention much better than a loop.
  - Someone else will appreciate it when the code is readable and easily understandable.
- Performance
  - Algorithms might perform better than handwritten loops

```cpp
std::vector<int> values{54, 23, 17, 95, 85, 57, 12, 9};
std::xxx(begin(values), end(values), ...);
```

13.1 Examples

13.1.1 for_each

```cpp
std::vector<unsigned> values{3, 0, 1, 4, 0, 2};

auto f = [](unsigned v) {};
std::for_each(begin(values), end(values), f);
```

13.1.2 merge

Merging two SORTED ragnes.

```cpp
std::vector<int> r1{9, 12, 17, 23, 54, 57, 85, 95};
std::vector<int> r2{2, 30, 32, 41, 49, 63, 72, 88};
std::vector<int> d(r1.size() + r2.size(), 0);
std::merge(begin(r1), end(r1), begin(r2), end(r2), begin(d));
```

13.1.3 accumlate

Sums elements are addabale (+) operator or based on a custom binary function.

```cpp
std::vector<std::string> longMonths{"Jan", "Mar", "May", "Jul", "Aug", "Oct", "Dec"};
std::string accumulatedString = std::accumulate(
  next(begin(longMonths)), //Second element
  end(longMonths), //End
  longMonths.at(0), //First element, usually the neutral element
  [](std::string const & acc, std::string const & element) {
    return acc + ", " + element;
}); //Jan, Mar, May, Jul, Aug, Oct, Dec
```

13.2 Pitfalls

Mismatching Iterator Pairs It is mandatory that the iterators specifying a range need to belong to the same range. Advancing the "first" iterator has to reach the "last" iterator eventually (without leaving the range).

Reserving Enough Space If you use an iterator for specifying the output of an algorithm you, need to make sure that enough space is allocated

Input Validation Some operations on containers invalidate its iterators.

14 Function Templates

- Can be compared to a Generic in Java. The keyword "template" is used to declare a template.
- The template parameter list contains one or more templates parameters.
- C++ uses duck-typing. So every type can be used as argument as long as it supports the used operations.
- Function templates are normally defined and implemented in a header file.
- Tempalate functions are implicitly inline
- We can write generics with templates.

The compiler resolves the function template and figures out the template arguments.

```
template <Template-Parameter-List>
FunctionDefinition
```

Template Definition
Templates are usually defined in a header file. Type checking happens twice: When the template is defined: Only basic checks are performed: syntax and resolution of names that are independent of the template parameters, When the template is instantiated (used): The compiler checks whether the template arguments can be used as required by the template.

```
// file min.h - Template definition
template <typename T>
T min(T left, T right) {
  return left < right ? left : right;
}
// file smaller.cpp - Template usage
#include "min.h"
#include <iostream>
int main() {
  int first;
  int second;
  if (std::cin >> first >> second) {
    auto const smaller = min(first, second); std::cout << "Smaller of " << first << "
     and " << second << " is: " << smaller << '\n';
  }
}
```

Template Instantiation
The Compiler: resolves the function template, figures out the themplate arguments, instantiates the template for the arguments, checks the types for correct usage.

Template Argument Deduction The compiler will try to figure out the function template's arguments from the call. Pattern matching on the function parameter list is used for deducing the correct argument.

14.1 Variadic Templates

- For function templates with an arbitrary number of parameters
- Needs at least one pack parameter
- Pack Expansion: For each argument in that pack an instance of the pattern is created
- In an instance of the pattern the parameter pack name is replaced by an argument of the pack
- Needs a base case for the recursion (after the last parameter is done, it would call the function without a parameter, which is invalid) → Base case must be written before the template function.

```
#include <iostream>
#include <string>

// Base Case
void printAll(std::ostream & out) {
}

template<typename First, typename...Types>
void printAll(std::ostream & out, First const & first, Types const &...rest) {
  out << first;
  if (sizeof...(Types)) {
```

```
12      out << ", ";
13    }
14    printAll(out, rest...);
15  }
16
17  int main() {
18    int i{42}; double d{1.25}; std::string book{"Lucid C++"};
19    printAll(std::cout, i, d, book);
20  }
```

14.1.1   Overloading

Multiple function templates with the same name can exist. As long as they can be distinguished by their parameter list.

15 Class Templates

- In addition to functions also class types can habe template parameters
- Since C++17, similar to function templates, the compiler might deduce the template arguments
- Class templates deliver types with compile time parameters
- Member function which never are used are also never compiled
- Compile-time polymorphism
- Class templates can be specialized

Rules

- Define class templates completely in header files!
- Member functions of class templates
    - Either in class template directly
    - Or as inline function templates in the same header file
- When using language elements depending directly or indirectly on a template parameter, you must specify typename when it is naming a type.
- static member variables of a template class can be defined in header without violating ODR, even if included in several compilation units.

```cpp
template <TemplateParameters>
class TemplateName { /*...*/ };

template <typename T>
class Stack { /*...*/ };
```

15.1 Template Argument Deduction (C++17)

Similar to function templates, the compiler might deduce the template arguments. This is a compile-time polmorphism.

```cpp
std::vector newValues{1, 2, 3}; // The compiler can deduce the type
std::vector<int> emptyValues{};
```

15.2 Type Alias & Dependent Names

- It is common for template definitions to define type aliases in order to ease their use.
- Within the template definition you might use names that are directly or indirectly depending on the template parameter.
- Dependent Name: Compiler geht standardmässig davon aus, dass es sich im eine Variable, oder eine Funktion handelt. Wenn es ein Typ ist (wie size_type), muss das keyword typename verwendet werden.

Example

```cpp
template <typename T> // Class template with one typename par
class Sack {
  using SackType = std::vector<T>;
  using size_type = typename SackType::size_type; // dependent name
  SackType theSack{};

public:
  bool empty() const {
    return theSack.empty();
  }
  size_type size() const {
    return theSack.size();
  }
  void putInto(T const & item) {
```

```
15      theSack.push_back(item);
16    }
17    T getOut(); // member forward declaration
18 };
```

Define the function outside of the template class definition.

```
1 template <typename T>
2 inline T Sack<T>::getOut() { // implementation outside of class
3   if (empty()) {
4     throw std::logic_error{"Empty Sack"};
5   }
6   auto index = static_cast<size_type>(rand() % size());
7   T retval{theSack.at(index)};
8   theSack.erase(theSack.begin() + index);
9   return retval;
10 }
```

15.3 Inheritance

Rule: Always use this->variable (or className::) to refer to inherited members in a template class.

16 Dynamic Heap Memory Management

Always rely on library classes for managing resource handling.

16.1 When ist Heap Memory used?

- Stack memory is scarce, most of the time about 1-2MB
- It might be needed for creating object structures.
- Also needed for polymorphic factory functions to class hierarchies.
- Resource Acquisition Initialization (RAII) Idiom

16.2 Legacy Heap Memory

Dont use this!

C++ allows allocating objects on the heap directly. If done manually, you are responsible for deallocation and risk undefined behaviour. This will mostly result in Memory leaks, Dangling pointers and Double deletes. The programmer is responsible to allocate and free all the memory used.

```cpp
// dont use new / delete
auto pr = new int{};
std::cout << *ptr << '\n';
delete ptr;
```

16.3 Modern Heap Management (C++11)

In the modern C++ world we can use smart pointers, which are C++ templates, to make memory management easier. With these smart pointers we dont have to call "delete ptr;" by ourselfs. Still: always prefer storing the value locally as value-type variable (Stack-based or member).

- Delete Pointer - must never be called.
- Unique Pointer - for unshared Heap Memory (cant be copied, can be moved).
- Shared Pointer - for shared Heap Memory (work as Java references, can be copied and moved).
- If the last "shared_ptr" handle gets destroyed, the allocated object gets deleted.
- Shared Pointer have the problem of cycles. For this reason there is a "weak_ptr" to break the cycles.

16.3.1 std::unique_ptr<T>

- defined in `#include <memory>`
- Uses the factory method `std::make_unique<T>()`
- Used for unshared heap memory
  - Or for local stuff that must be on the heap
  - Can be returned from a factory function
- Only a single owner exists
- Not the best for class hierarchies
- Can not be copied

Use Cases

- As member variable
- As local variable

```cpp
#include <iostream>
#include <memory>
#include <utility>

std::unique_ptr<int> create(int i) { // transfer of ownership through return by value
  return std::make_unique<int>(i);
}

int main() {
  std::cout << std::boolalpha;
  auto pi = create(42);
  std::cout << "*pi = " << *pi << '\n';
```

```
13    std::cout << "pi.valid? " << static_cast<bool>(pi) << '\n';
14    auto pj = std::move(pi); // explicit transfer of ownership
15    std::cout << "*pj = " << *pj << '\n';
16    std::cout << "pi.valid? " << static_cast<bool>(pi) << '\n';
17 }
```

16.3.2   shared_ptr<T>

- Works more like a Java reference and allows multiple owners.
- Therefore it can be copied, passed around.
- Has a reference counter on the heap object. Object gets destructed as soon as there are no references left.
- The pointer is `std::shared_ptr` and associates objects of Type T using `std::make_shared<T>()`.
- If instances of a class hierarchy are always represented by a `std::shared_ptr<base>` but created through `std::make_shared<concrete>()` the destructor no longer needs to be virtual.
- Can lead to object cycles no longer cleared, because of circular dependency

```
1 struct Article {
2   Article(std::string title, std::string content);
3   //..
4 };
5 Article cppExam{"How to pass CPl?", "In order to pass the C++ exam, you have to..."};
6 std::shared_ptr<Article> abcPtr = std::make_shared<Article>("Alphabet", "ABCDEFXYZ");
```

Use Cases

- If you really need heap-allocated objects, because you create your own object networks
- If you need to support run-time polymorphic container contents or class members that can not be passed as reference, e.g., because of lifetime issues
- Factory functions returning std::shared_ptr for heap allocated objects.
- But first check if alternatives are viable:
    - (const) references as parameter types or class members
    - Plain member objects or containers with plain class instances

The usage is counted on the referenced object to keep track of how many reference currently point to this object on the heap.

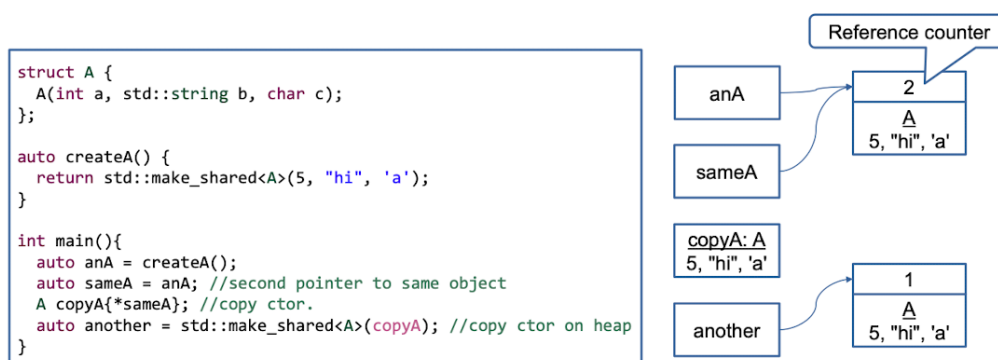

Figure 15: Shared Pointer

16.3.3   std::weak_ptr<T>

- The `shared_ptr<T>` cycles need to be broken for nesting and object networks and this can be done with `weak_ptr<T>`.
- `weak_ptr` does not allow direct access to the object
- A `weak_ptr` does not know weather the pointer is still alive
- with `lock()` to the object can be acquired if alive.

```
struct Person {
  std::shared_ptr<Person> child;
  std::weak_ptr<Person> parent;
};

int main() {
  auto anakin = std::make_shared<Person>();
  auto luke = std::make_shared<Person>();
  anakin->child = luke;
  luke->parent = anakin;
  //...
}
```

Figure 16: Weak Pointer

Access with std::weak_ptr
As mentioned a weak ptr does not know whether the pointee is still alive. `std::weak_ptr::lock()` return a `std::shared_ptr` that either points to the alive pointee or is empty.
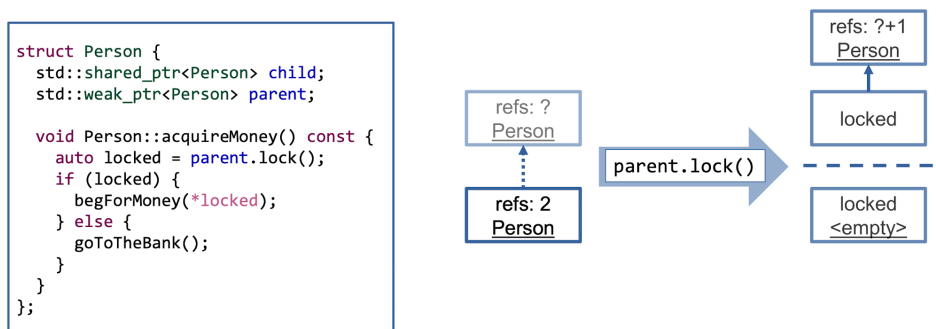

```
struct Person {
  std::shared_ptr<Person> child;
  std::weak_ptr<Person> parent;

  void Person::acquireMoney() const {
    auto locked = parent.lock();
    if (locked) {
      begForMoney(*locked);
    } else {
      goToTheBank();
    }
  }
};
```

Figure 17: Shared Pointer Access Check with Lock

Spawning Children from parents
This can be done if we inherit from `std::enable_shared_from_this<T>`. Then we can access the function `weak_from_this();` to create a reference to the parent.
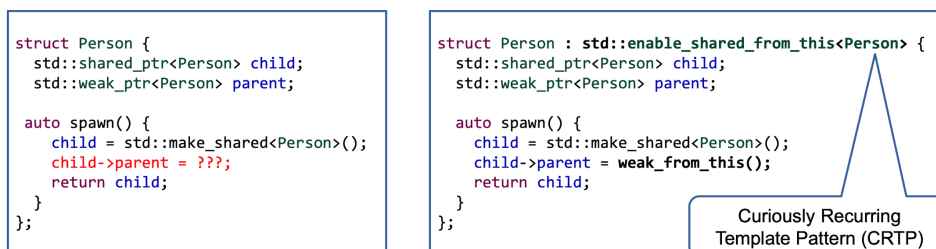

```
struct Person {
  std::shared_ptr<Person> child;
  std::weak_ptr<Person> parent;

 auto spawn() {
    child = std::make_shared<Person>();
    child->parent = ???;
    return child;
  }
};
```

```
struct Person : std::enable_shared_from_this<Person> {
  std::shared_ptr<Person> child;
  std::weak_ptr<Person> parent;

  auto spawn() {
    child = std::make_shared<Person>();
    child->parent = weak_from_this();
    return child;
  }
};
```

Curiously Recurring
Template Pattern (CRTP)

Figure 18: Enable Shared Parent Creation

45

17 Inheritance

Inheritance is always then used, when specific components want to be reused and extended. Inheritance can be bad because it creates a very strong dependency.

- Inheritance is default public (structs). For classes the inheritance is private.
- The constructors are not inherited implicitly we have to specify that.
- The parent is always constructed first and after that the children.
- Assining or send parameters per value from an inherited class to the base class result in **Object Slicing**.

```cpp
class MyClass : Base {}; // implicit private
struct MyStruct : Base {}; // implicit public

class MyClass : public Base {
  public:
    using Base::Base; // inherit constructor
};
```

17.1 Initialising Multiple Base Classes

Base constructors can be explicitly called in the member initializer list. You should put base class constructor class before the initialization of members. The compiler enforces this rule, even though you can put the list of initializers in wrong order.

```cpp
class DerivedWithCtor : public Base1, public Base2 {
  int mvar;
public:
  // calls base1, base2, mvar
  DerivedWithCtor(int i, int j) : Base1{i}, Base2{}, mvar{j} {}
};
```

17.2 Dynamic Polymorphism

- Operator and function overloading and templates allow polymorphic behaviour at compile time
- Basae class is required to have virtual member functions
- Dynamic polymorphism needs object references or (smart) pointers to work
  - Syntax overhead
  - The base class must have a good abstratction
  - Copying carries the danger of slicing (partial copying)

17.2.1 Shadowing Member Functions

- if a function is reimplemented in a derived class, it shadows its counterpart in the base class
- However, if accessed through a declared bases object, the shadowing function is ignored

```cpp
struct Base {
  // shadowed function
  void sayHello() const {
    "Im Base\n"
  }
}
struct Derived : Base {
  // shadowing function
  void sayHello() const {
    std::cout << "hi, im derived\n";
  }
};
void greet(Base const & base) {
  base.sayHello();
}
in main() {
  Derived derived{};
  greet(derived); // Hi, im Base (static call)
}
```

17.3   Virtual Member Functions

- To achieve dynamic polymorphism "virtual" member functions are required
- "Virtual" member functions are bound dynamically.
- The virtual keyword ist automatically inherited and does not have to be restated at childs.
- The sub needs to state overriding functions with "override"
- To override a virtual function the signatures has to be the same! (constnes included)

```cpp
struct Base {
  virtual void sayHello() const {
    std::cout << "Hi, I'm Base\n";
  }
};

struct Derived : Base {
  void sayHello() const { // virtual is automatically inhertited
    std::cout << "Hi, I'm Derived\n";
  }
};
void greet(Base const & base) {
  base.sayHello();
}

int main() {
  Derived derived{};
  greet(derived); // Hi, I'm Derived (dynamic call)
}
```

17.4   Calling Virtual Member Functions

- Value Object
    - Class type determines function, regardless of virtual
- Reference
    - Virtual member of derived class called through base class reference
- Smart Pointer
    - Virtual member of derived class called through smart pointer to base class
- Dump Poiner (rarely used)
    - Virtual member of derived class called through base class pointer

```cpp
void greet(Base base) {
  base.sayHello(); // Value: always calls base
}

void greet(Base & base) {
  base.sayHello(); // Reference: dynamic binding
}

void greet(std::unique_ptr<Base> base) {
  base.sayHello(); // dynamic binding
}

void greet(Base const * base) {
  base->sayHello(); // dynamic binding
}
```

17.5   Abstract Base Classes

- There are no Interfaces in C++
- A pure virtual member function makes a class abstract
- To mark a virtual member function as pure virtual it has zero assigned after its signature
- Abstract classes cannot be instantiated (like in Java)

```cpp
struct abstractBase {
  virtual void doitnow() = 0;
}
```

17.6   Destructors

- Classes with virtual members require a virtual Destructor
- Otherwise when allocated on the heap with make_unique and assigned to a unique_ptr only the destructor of Base is called
- `std::shared_ptr<T>` memorizes the actual type and knows which destructor to call.

```cpp
struct Fuel {
  virtual void burn() = 0;
  virtual ~Fuel() { std::cout << "put into trash\n" }
};

struct Plutonium : Fuel {
  void burn() { std::cout << "split core\n"; }
  ~Plutonium() { std::cout << "store many years\n"; } // automatically inherits
     virtual
};

int main() {
  std::unique_ptr<Fuel> surprise = std::make_unique<Plutonium>(); // both called
}
```

17.7   Object Slicing

Assigning or passing by value a derived class value to a base class variable/parameter incurs object slicing. Only base class member variable are transferred.

```cpp
struct Base {
  int member{};
  explicit Base(int initial) :
    member{initial}{}
  virtual ~Base() = default;
  virtual void modify() { member++; }
  void print(std::ostream & out) const;
};
struct Derived : Base {
  using Base::Base; // inherit constructor
  void modify() { member += 2; }
};
// main.cpp
void modifyAndPrint(Base base) {
  base.modify();
  base.print(std::cout);
}
int main() {
  Derived derived{25};
  modifyAndPrint(derived);  // Output: 26
}
```

The object slicing problem can be solved if we set the copy operations as delted.

```cpp
struct Base {
  Base & operator=(Base const & other) = deleted;
  Book(Book const & other) = deleted;
}
```

17.8   Member Hiding

Member functions in derived classes hide base class member with the same name, even if different parameters are used. By using the base class member we can solve the problem.
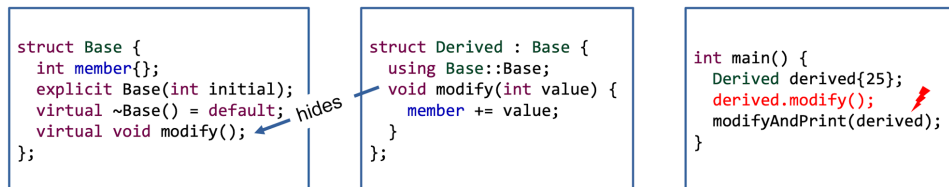

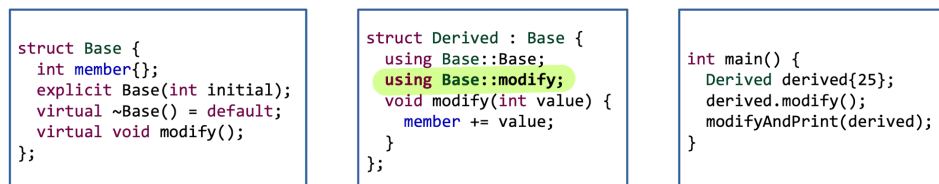

Figure 19: Member Hiding Problem

Figure 20: Member Hiding Problem Solution

18 Initialisation

- Default Initialization
- Value Initializtaiton
- Direct Initialization
- Copy Initialization
- List Initialization
- Aggregate Initialization

18.1 Default Initialization

Is the simplest type of initialization. We simply don't provide an initializer. This depends on the kind of entity we want to declare. This does not work for references! Also does not rally work with a const object.

```cpp
int global_variable; // implicitly static
void di_function() {
  static long local_static; // Default I
  long local_variable; // Default I
}
struct di_class {
  di_class() = default; // Default Initializer
  char member_variable; // not in ctor init list
};
```

Effects

- Static Variables are Zero initialized first, then their types default constructor is called.
- Non static integer and floating point variable are unitialized!
- Object of class types are constructed using their default constructor.
  - Member Variables not in a ctor-init-list are default initialized
- Arrays initialized all of their elements accordingly

```cpp
struct blob {
  blob(int); // suppreses default constructor
};
blob static_instance; // error no matching function blob::blob();!
```

```cpp
void di_function() {
  long local_variable; // no initialization
  std::string local_text; // gets default constructed, string default constructor
}
struct di_class {
  di_class() = default;
  char member_variable; // default initiliazed, since value type the content is
    rubbish
};
```

18.2 Value Initialization

Value Initialization is perfomed with empty (), {} but currly brackets are prefered, since it works with more classes. Invokes the default constructor for class types.

```cpp
#include <string> #include <vector>
void vi_function() {
  int number { };
  std::vector<int> data { };
  std::string actually_a_function(); // Is a function and not a variable!!
}
```

18.3   Direct Initialization

Nearly the same as Value initialization but we directly define the value. Using **{}** only applies to non class types.

```
1 #include <string>
2 void diri_function() {
3   int number{32}; // DI
4   std::string text("CPL"); // DI
5   word vexing (std::string()); // Most Vexing Parse
6 }
```

Most Vexing Parse   There are two interpretations of this expression: Initialization with a value-initialiized string, Decleration of a function returnin g a word and taking an unnamed pointer to a function returning a string.

18.4   Copy Initialization

Initialization using **=**.
Pseudocode for behavior of copy initialization.

```
1 if(object has type class, rhs has the same type)
2   if(rhs is temporary) object is constructed in place
3   else( copy constructor is invoked )
4 else(Suitable conversion sequence is searched for)
```

```
1 #include <string>
2 std::string string_factory() { return ""; }
3
4 void ci_function() {
5   std::string in_place = string_factory(); // object in place
6   std::string copy = in_place; // copy constructor
7   std::string converted = "CPl"; // converted
8 }
```

18.5   List Initialization

Uses the non empty **{}**. If there is a suitable constructor takin **std::initializer_list** is selected. Otherwise a suitable constructor is searched.

```
1 // Direct List Initialization
2 std::string direct { "CPI" };
3 // Copy List Initialization
4 std:: string copy = { "CPIA" };
```

Pittfall   Since the **std::itializer_list** constructor is preferred, you might run into trouble.

```
1 int ouch() {
2   std::vector<int> data {10, 42}; // creates with initializer list.
3   return data[5]; // out of bound!
4 }
```

19 Aggregates

Is a simple class type.

- Can have other types as public class types
- Can have member variables and functions
- Must not have user-provided, inherited or explicit constructors
- must not have protected or private direct members

```cpp
struct person {
  std::string name;
  int age{42};

  bool operator<(person const & other) const {
    return age < other.age;
  }

  void write(std::ostream & out) const {
    out << name << ": " << age << "\n";
  }
};

int main() {
  person rudolf{"Rudolf", 32};
  rudolf.write(std::cout);
}
```

19.1 Aggregate Initialization

Conecptional a special case of the list initialization. If the type is an aggregate, the members and base classes are initialized from the initializers in the list.

```cpp
person rudolf{"Rudolf"};
```
